INTRODUCTION – PREVIOUS EXPERIENCE

¿Why did we choose Arena Rockwell software for DES modeling?

- A colleague had previously worked with Arena.
- I had not used R before (neither for statistical analysis)
- It had a good tutorial book with examples and a student demo version.

 The software has pre-specified modules, you only need to know which is the aim of each type of module and how to fulfill the parameters.

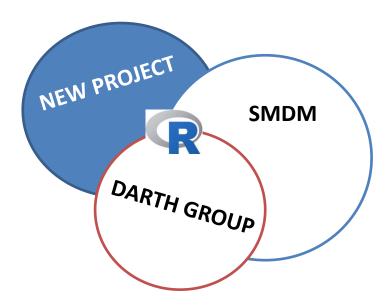

Random number generators for different probability distributions.

INTRODUCTION – PREVIOUS EXPERIENCE

Difficulties using Arena Rockwell software for DES modeling

- Read data for parameter values.
- Incorporate parameter uncertainty in the model
- Write data for posterior analysis.

In 2016 we changed our mind:

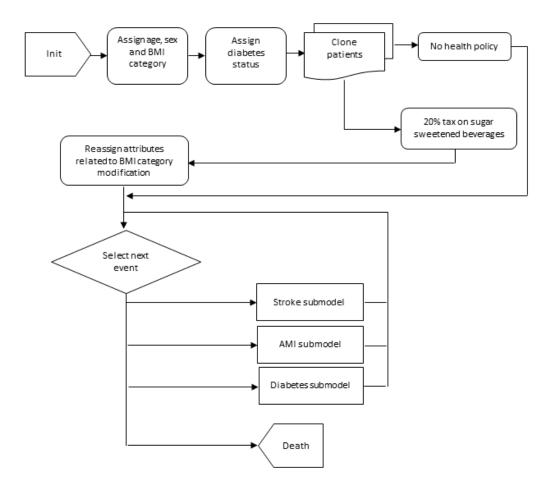

CONCEPTUAL MODEL AND INPUT PARAMETERS

NEW PROJECT

HEALTH AND ECONOMIC EFFECTS OF A SUGAR SWEETENED BEVERAGE TAX IN THE SPANISH POPULATION

Main Objective: The objective of this project is to analyze the impact on health and costs of two health policies aimed at reducing the consumption of salt and sugary drinks in the Spanish population by using discrete event simulation.

CONCEPTUAL MODEL AND INPUT PARAMETERS

In order to reproduce the whole Spanish population:

Data set 1: National Statistics Centre. Alive population by age and sex.

- Sex: proportion of female population ~ Binomial distribution
- Birth date: Empirical distribution depending on Sex

Data set 2: National Health Survey 2011-2012.

- Social Status: depending on Sex and Age ~ Multinomial regression
- BMI category: depending on Sex, Age and Social Status ~ Multinomial regression

Based on previously published papers:

Impact of 20% tax	Overweight	-0.4%	Briggs et al. 2013
	Obesity	-1.3%	
All-cause mortality in obesity	Normal weight	1.00	Flegal et al. 2013
(Hazard ratio)	Overweight	0.92	
	Obesity	1.21	

CONCEPTUAL MODEL AND INPUT PARAMETERS

Data set 3: National Statistics Centre. Mortality rates by age and sex.

Data set 4: Minimum Hospitalization Data Base (2009-2013).

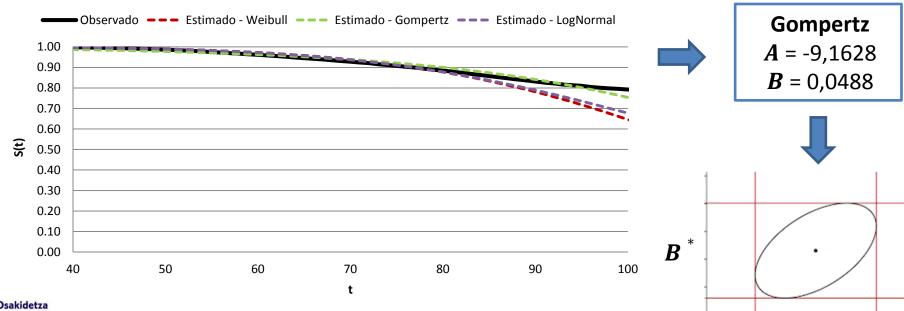

Stroke (ICD-9 430-438)

Acute myocardial infarction (ICD-9 410)

Classify first and successive events in 2013.

9

Survival curve

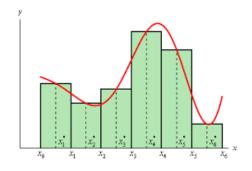

In order to estimate quality-adjusted life years in our model:

Spanish Health Survey performed in 2012

- 21,007 adults
- EuroQol 5D-5L questionnaire: 63% in perfect health, mean = 0.91.

- Utilities ranged $(-\infty, 1]$
- High proportion of perfect health (utility equal to one)
- Two-part models ensure that estimated values will never adopt values higher than 1, while also allowing for negative mean utility values

The **two part model** is based on the decomposition of the mean utility value u(x) as follows:

$$u(x) = p(x) \cdot 1 + (1 - p(x)) \cdot (1 - w(x))$$

First, a logistic regression model:

$$\log(\frac{p(x)}{1 - p(x)}) = Beta_1 \cdot x$$

Second, the individuals not in perfect health are sub-selected and a generalized linear model (with log link if necessary) is applied to the disutilities (i. e. 1 - u(x)).

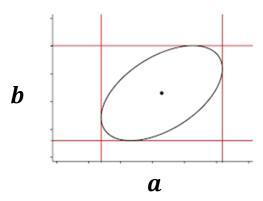

$$link(E(w(x))) = link(E(1 - u(x))) = Beta_2 \cdot x$$

and their correspondent variance-covariance matrixes (V_1, V_2) .

SECOND-ORDER UNCERTAINTY

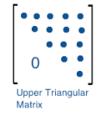

$$Y \sim a + b \cdot X$$

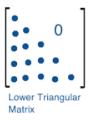

CHOLESKY DESCOMPOSITION

According to the methodology described in detail by Briggs et al., the Cholesky decomposition of the variance-covariance matrixes (V_1, V_2) will yield the correspondent lower triangular matrixes (T_1, T_2)

 $V_i = T_i * T_i'$, where T_i' is T_i transposed for i = 1, 2

SECOND-ORDER UNCERTAINTY

- Let it be (Beta₁, Beta₂) the estimated coefficients vector and (T_1, T_2) the triangular matrixes obtained by Cholesky descomposition of (V_1, V_2) .
- (Z_1, Z_2) randomly generated vectors where each value follows a standard Normal distribution $(Z \sim N(0,1))$. Same length as $(Beta_1, Beta_2)$.
- New regression parameters (Beta₁*, Beta₂*) were calculated as follows:

Beta
$$_{1}^{*}$$
 = Beta $_{1}$ + ($T_{1} * Z_{1}$)

Beta
$$_{2}^{*}$$
 = Beta₂ + ($T_{2} * Z_{2}$)

Thus, the parameters used to estimate mean utility values in the first simulation of our cost-effectiveness model were:

STEP 1

$$Beta_1 = (1.02, -0.04, 0.77, -0.65, 0.38, 0.52, -0.06, -0.52, -0.03, -0.01, -0.18, 0.01, -0.30, 0.13)$$

$$Z_1 = (0.56, -0.45, 0.58, 0.17, 2.91, -0.63, 0.89, 1.02, 1.11, -1.02, -0.78, 0.30, -0.98, 0.59)$$

$$T_1 * Z_1 = (-0.15, 0.00, 0.10, -0.09, 0.22, -0.09, 0.06, 0.07, 0.01, 0.00, -0.04, 0.02, -0.07, 0.07)$$

Beta
$$_{1}^{*}$$
 = Beta₁ + ($T_{1} * Z_{1}$)

Beta
$$_{1}^{*} = (0.87, -0.04, 0.88, -0.73, 0.60, 0.43, -0.01, -0.45, -0.02, -0.00, -0.21, 0.03, -0.36, 0.20)$$

STEP 2

 $Beta_2 = (-1.74, 0.01, -0.53, 0.08, -0.03, -0.18, -0.01, 0.21, 0.02, 0.00, -0.06, 0.11, -0.03, 0.17)$

$$Z_2 = (-0.97, 0.84, 0.21, -1.06, 0.01, -0.98, 1.21, -1.56, -0.10, 1.55, 0.78, 0.13, -0.34, 1.22)$$

$$T_2 * Z_2 = (0.05, 0.01, 0.03, 0.02, -0.02, -0.11, 0.00, -0.06, -0.01, -0.01, 0.02, 0.01, -0.01, 0.08)$$

$$Beta_2^* = Beta_2 + (T_2 * Z_2)$$

Beta $^*_2 = (-1.69, 0.01, -0.50, 0.10, -0.05, -0.29, -0.00, 0.15, 0.01, -0.00, -0.03, 0.11, -0.04, 0.25)$

Following the detailed procedure we will explain in the following example how to sample utility values for in each simulation of a cost-effectiveness analysis model:

Sex = Men

Age = 10 (60 years - 50 mean age)

Social status = High

Body mass index (BMI) < 25 (normal weight)

Models included also interactions between:

Sex and age

Social status and BMI

$$\begin{array}{l} \text{Beta} \ _1^* \ = \ (0.87, -0.04, 0.88, -0.73, 0.60, 0.43, -0.01, -0.45, -0.02, -0.00, -0.21, 0.03, -0.36, 0.20) \\ \text{Beta} \ _2^* \ = \ (-1.69, 0.01, -0.50, 0.10, -0.05, -0.29, -0.00, 0.15, 0.01, -0.00, -0.03, 0.11, -0.04, 0.25) \\ \end{array}$$

Therefore, in the first step (Logistic regression):

$$ln\left(\frac{p(x)}{1-p(x)}\right) = \mathbf{0.87} - \mathbf{0.04} * (60-50) + \mathbf{0.43} = 0.90$$
$$p(x) = \frac{exp(0.90)}{1+exp(0.90)} = 0.7109$$

And in the second step (GLM, logartimic link):

$$ln(w(x)) = -1.69 + 0.01(60 - 50) - 0.29 = -1.88$$

$$w(x) = exp(-1.88) = 0.1526$$

The estimated mean value using the two part regression analysis would be:

$$p(x) = 0.7109$$

$$w(x) = 0.1526$$

$$u(x) = p(x) \cdot 1 + (1 - p(x)) \cdot (1 - w(x))$$

= 0.7109 + (1 - 0.7109) * (1 - 0.1526) = **0.9559**

So, based on this regression model, **71.09**% of the selected subpopulation was assumed in perfect health, and the estimated mean utility value for those not in perfect health was **0.8474** (= 1- 0.1526).

In fact, <u>using matrix operators</u> in R it takes few code lines to estimate individual characteristics adjusted utilities using the corresponding coefficients in each run.

$$T_1 = Chol(V_1); T_2 = Chol(V_2);$$

$$Beta_1^* = Beta_1 + (T_1 * Z_1)$$

$$Beta_2^* = Beta_2 + (T_2 * Z_2)$$

$$p(\mathbf{x}) = \frac{exp(\text{Beta }_{1}^{*} \cdot \mathbf{x})}{1 + exp(\text{Beta }_{1}^{*} \cdot \mathbf{x})}$$

$$w(\mathbf{x}) = exp(\text{Beta }_2^* \cdot \mathbf{x})$$

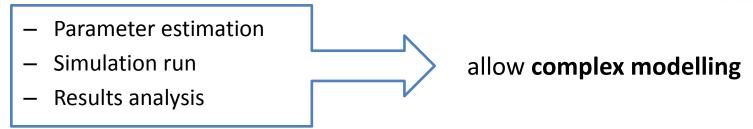

$$u(\mathbf{x}) = p(\mathbf{x}) \cdot 1 + (1 - p(\mathbf{x})) \cdot (1 - w(\mathbf{x}))$$

CONCLUSIONS

Using the same software for:

- We work in R code that use data bases without modifying the original source.
- Using matrix operators to assign attributes reduce simulation time.
- Collaborative work, all methodological improvements can be public.

Thank you Eskerrik asko
